The phasor of the voltage amplitude of the entire circuit is represented by light blue. A phase difference between the voltage and the current is said to be the angle  $\phi$  between the current phasor and the overall voltage phasor. The angle  $\phi$  is drawn by navy blue ; For an RLC circuit and the given quantities the phasor diagram looks like this:

A circuit breaker in series before the parallel branches can prevent overloads by automatically opening the circuit. A 15 A circuit operating at 120 V consumes 1,800 W of total power.  $P = VI = (120 \text{ V})(15 \text{ A}) = 1,800 \text{ W}$ . Total power in a parallel circuit is the sum of the power consumed on the individual branches.
